Acknowledgments

We would like to thank all of the interested parties who provided us with observation charts from their hospital or area health service for inclusion the current study.

We thank Nicola Dunbar from the Commission and Jillann Farmer from the Patient Safety Centre, Queensland Health for their support throughout the project, and Alexandra Sonsie from the Commission for assembling the majority of the observation charts and distributing the recruitment email to potential respondents.

We also thank Kirsten Price for her comments on the survey items and John Manly for research assistance.

Executive Summary

The current study was the second stage of a project funded by the Australian Commission for Quality and Safety in Health Care and Queensland Health to investigate the design and use of observation charts in recognising and managing patient deterioration, including the design and evaluation of a new adult observation chart that incorporated human factors principles.

Improving the recognition and management of patients who deteriorate whilst in hospital is a frequently cited goal for patient safety. Changes in physiological observations or ‘vital signs’ commonly precede serious adverse medical events. Paper-based observation charts are the chief means of recording and monitoring changes to patients’ vital signs. One approach to improve the recognition and management of deteriorating patients is to improve the design of paper-based observation charts (note that the management of patient deterioration can potentially be affected by chart design if, for example, action plans are included on the chart).

There is considerable variation in the design of observation charts in current use in Australia and a lack of empirical research on the performance of observation charts in general. The aim of the current study was to gauge the opinions of the population who actually use observation charts.

We recruited a large sample of health professionals (N = 333) to answer general questions about the design of observation charts and specific questions about nine observation charts. The participants reported using observation charts daily, but only a minority reported having received any formal training in the use of such charts.

In our previously-reported heuristic analysis of observation charts (1), we found that the majority of charts included a large number of abbreviations. In this survey, participants were asked to nominate which term they first thought of when seeing a particular abbreviation. Most abbreviations were overwhelmingly assigned the same meaning. However, some abbreviations had groups of participants nominating different terms for the same abbreviation. Participants were also asked to nominate their preferred terms for nine vital signs that commonly appear on observation charts. For some vital signs, there was a high level of agreement as to which term was easiest to understand; however, for other vital signs, there was no clearly preferred term.

Participants were also asked about their chart design preferences both in terms of (a) recording observations and (b) detecting deterioration. In both instances, participants preferred the option to “Plot the value on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality”. Participants’ preference was in line with what a human factors approach would recommend (i.e. charts with a colour-coded track and trigger system).

In the final sections of the survey, participants were first asked to respond to 13 statements regarding the design of their own institution’s current observation chart, and then to respond to the same 13 statements for one of nine randomly-assigned observation charts. The nine observation charts included the new Adult Deterioration Detection System (ADDS) chart and eight charts of “good”, “average”, or “poor” design quality from the heuristic analysis.
Participants’ mean aggregated rating across the 13 items for their institution’s current observation chart was close to the scale’s mid-point, $3 = \text{neutral}$. For the assigned charts, there was a statistically significant effect of chart type on the aggregated rating. The \textit{a priori} “poor” quality charts were each rated as having a significantly poorer design compared with each of the other charts (collectively, the \textit{a priori} “average” and “good” quality charts). There was partial support for our hypothesis that health professionals would rate the “good” charts as having better design, compared to the “average” and “poor” charts.

In conclusion, the online survey served two main purposes. First, it collected quantitative data on health professionals’ general preferences regarding aspects of the design of observation charts. This information informed the design of the ADDS chart and could also be used by other chart designers to produce more user-friendly hospital charts. Second, the online survey enabled health professionals to rate the design of the new ADDS chart as well as eight existing charts of varying quality. Overall, health professionals agreed with our human factors-based rating with regards to the “poor” quality charts. However, the health professionals did not differentiate between the “average” and “good” quality charts in their ratings.
**1. Project Background**

1.1 General background

Improving the recognition and management of patients who deteriorate whilst in hospital is a priority both at the national and state level. The Australian Commission on Safety and Quality in Health Care (ACSQHC) has launched a national program for ‘Recognising and Responding to Clinical Deterioration’ (2). In parallel, Queensland Health’s Patient Safety Centre has released a strategy options paper discussing gaps in the recognition and management of the deteriorating patient (3).

Changes in physiological observations or ‘vital signs’ commonly precede serious adverse events such as cardiac or respiratory arrest, unplanned Intensive Care Unit (ICU) admission, or unexpected death (4-9). Several studies report that derangements in vital signs are observable up to 48 hours before the adverse event (4, 6, 7, 10). This suggests that if deterioration is recognised early and appropriately managed, then complications arising from delays could be reduced (e.g. morbidity, unexpected ICU admissions, extended length of stays in hospital), and some serious adverse events could potentially be avoided altogether (11-14).

Paper-based observation charts are the principal means of recording and monitoring changes to patients’ vital signs. However, vital signs are not always correctly recorded or appropriately acted upon (4, 7, 10, 11, 15). The design of the observation charts themselves may contribute to failures in the ability of medical and nursing staff to record vital signs and recognise deterioration.

There is considerable variation in the design of observation charts in current use in Australia. They vary in both the number and selection of vital signs monitored. Observation charts also display diversity in the way in which information is presented. For instance, respiration rate may be displayed on one chart as a row containing boxes in which to write the number of breaths taken by a patient per minute at each time-point, while on another chart it may be plotted as a graph over time. Finally, observation charts also vary in the degree to which they incorporate track and trigger systems based on clinical criteria to help users recognise a deteriorating patient and respond appropriately.

There is presently a lack of empirical research on the design and use of observation charts. In Australia, observation charts tend to be designed at the local hospital or individual health service area level, resulting in a nationwide duplication of effort (11). Some observation charts appear to have been trialled in specific wards before full implementation or evaluated by means of a staff survey. Rigorous empirical evaluation is lacking in most cases.

There are indicative findings that efforts to improve the design of observation charts can produce benefits for patients, staff, and the hospital. In the United Kingdom, Chatterjee et al. carried out an empirical evaluation of five observation charts in use at a district general hospital (16). They reported that the design of the charts had a significant effect on the ability of staff to recognise patient deterioration (with a detection rate as low as 0% for one vital sign), and that no single
existing chart was best for all vital signs. As a result, they designed and implemented a new chart incorporating a track and trigger system. They found that there was a significant improvement in staff’s ability to recognise deterioration (all detection rates over 90%), after the re-design and implementation of the new chart. Their new chart produced improvements in the detection of four forms of deterioration, hypoxia (45% increase in detection), tachypnoea (41% increase in detection), tachycardia (29% increase in detection), and fever (16% increase in detection). A recent Australian project to improve the early detection of patient deterioration, which included improvements to observation chart design (together with other interventions such as training), was found to produce statistically significant gains in the frequency of recording vital signs, as well as decreasing unplanned ICU admissions, decreasing the rate of cardiac arrests, and decreasing the rate of hospital deaths (17).

1.2 Background of the project

The current study was part of the second phase of a project funded by the Australian Commission for Quality and Safety in Health Care and Queensland Health to investigate the design and use of observation charts in recognising and managing patient deterioration, including the design and evaluation of a new adult observation chart that incorporated human factors principles. The initial phase of the project was a systematic usability evaluation of the quality and extent of design problems in 25 existing observation charts (1). A total of 1,189 usability problems were identified in the observation charts. Usability problems were identified as affecting the observation charts’ page layout, information layout, recording of vital signs, integration of track and trigger systems, language and labelling, cognitive and memory load, use of fonts, use of colour, photocopied legibility, and night-time legibility. In compiling lists of the various usability problems present in the observation charts, we produced a de facto manual for producing a better designed observation chart. The next step in the project was to design a new user-friendly observation chart that adhered to good design principles whenever possible.

1.3 The Adult Deterioration Detection System (ADDS) chart

Using the information obtained from the heuristic analysis, a new chart was designed by combining what were considered to be the best design features of existing charts (see 18 for an overview). The chart was largely based on: (a) The Prince Charles Hospital chart (Brisbane, Queensland), which in turn was based on the Compass chart developed at The Canberra Hospital, ACT Health, and (b) the Children’s Early Warning Tool (CEWT) paediatric chart developed at Royal Children’s Hospital (Brisbane, Queensland). The new chart was named the Adult Deterioration Detection System (ADDS) chart and incorporated the following features designed to minimize design problems that might lead to human error in both recording and interpreting patient data (see Appendix C to view the ADDS chart, labelled Chart 1). Note that the key function of the ADDS chart was to detect patient deterioration, rather than to act as a general observation chart.

- The ADDS chart featured both a single parameter and a multiple parameter colour-coded track and trigger system to facilitate the detection of deterioration. The single parameter
An Online Survey of Health Professionals’ Opinions Regarding Observation Charts

system (in which a medical emergency response was required when any single patient vital sign was outside a given range) had the advantage of simplicity of use. The multiple parameter system (in which vital signs were scored using a colour-coded key and scores were summed to give an overall indication of the patient’s condition) was potentially more sensitive to deterioration and could lead to earlier detection of deterioration or fewer false alarms (see reference 18 for further details).

- Chart colours were chosen such that colour density correlated with the extent to which the patient’s vital signs were outside the normal range (apart from being an intuitive progression, this strategy would aid colour-blind users).

- All information required for use (e.g. the colour key, the medical emergency criteria, and the actions to be taken when different levels of deterioration were detected) was provided on the same page as the vital signs data. This was in order to reduce cognitive load (e.g. to avoid the user having to turn the page to access more information).

- Only vital signs considered to be the most important for detecting deterioration were included on the chart. If additional information had been included, this less important information would potentially compete with the more important information for the user’s attention.

- Each vital sign was presented as a separate graph. Many existing charts either displayed data numerically (making it difficult to see data trends and hence making deterioration harder to detect) or included graphs with multiple vital signs plotted on the same graph area (this increased visual clutter, which could make deterioration harder to detect).

- The most critical vital signs were placed towards the top of the page, as this is where users would look first. Most existing charts did not follow this practice.

- Scales were labelled on both the left and right of each graph and bold vertical lines were placed every 3 columns. These features were designed to minimize the chance of users reading from the wrong column or row.

- There was space to record modifications to vital sign thresholds. This information was placed so that it would be in view when a user first picked up the chart.

1.4 Rationale for the current study

Before formally trialling the new observation chart, it was considered important to seek the opinions of the population who actually use observation charts. The aim of the online survey was to recruit a sample of relevant health professionals to answer general questions about the design of observation charts and specific questions about nine observation charts. The nine observation charts in the online survey included the new observation chart and eight observation charts of “good”, “average”,

10
or “poor” design quality according to the usability evaluation. It was hypothesised that health professionals would rate the “good” charts as having better design, compared to the “average” and “poor” charts.

2. Method

2.1 Participants

Participants (N = 333) were recruited via an invitation email sent by the ACSQHC on behalf of the Research Team. The email was sent to approximately 250 health professionals who had previously indicated their interest in patient deterioration. These individuals were also encouraged to forward the invitation to any colleagues who might be interested in participating (snowball method). Participants were offered the chance to win an Apple iPhone (valued at $879) if they completed the online survey by 30 November 2009.

2.2 Online Survey

The online survey was run using Checkbox Survey Software version 4.6. The survey comprised 82 items. The survey began with questions about the participants’ characteristics and their current use of observation charts. The second section of the survey assessed the comprehensibility of abbreviations commonly found in observation charts. For example, “What do you first think of when you see “P” on an Observation Chart?” (with the following response options: patient, pain, pulse or other). The third section of the survey asked participants to nominate their preferred terms for nine vital signs. For instance, “For temperature, which term do you think is the easiest for the average nurse to understand?” (with the response options being: Temperature, Temp, or T).

The next sections of the survey asked the same set of questions twice: once in relation to ‘recording vital signs’, and once in relation to ‘detecting deterioration’. The first question asked which chart layout participants preferred (with options ranging from writing the value in a box to plotting the value on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality). The second question asked whether participants preferred having blood pressure and pulse together on the same graph or on separate graphs. The third question asked if participants preferred having both systolic and diastolic blood pressure recorded on a chart, or systolic blood pressure alone.

The penultimate section of the survey required participants to use a Likert scale to indicate the extent to which they agreed with 13 statements about their institution’s current observation chart. The statements addressed the chart’s design, recording of vital signs, signaling of deterioration, response to deterioration, and support of staff’s clinical decision making. The final section of the survey presented images of one of nine observation charts to each participant. The participants then indicated their agreement with the same 13 statements for the presented chart. A final question
checked that the presented chart’s image was displayed on a participant’s computer screen (in case of technical hitches).

The response format for the questions typically involved selecting one option from a list of likely responses, or a Likert scale. However, an “other” option (with an accompanying blank field for typing a unique answer) was included for many of the items. Furthermore, participants were given a number of opportunities to make open-ended comments throughout the survey.

To minimise the time it took to complete the online survey, we took advantage of the Checkbox software’s ‘conditions’ function where appropriate. For example, if a participant answered No to the item, “Do you record information in Observation Charts as part of your current role?”, a further question regarding the frequency the participant recorded information in charts was omitted. A copy of the full survey is available in Appendix A.

2.3 Design and Procedure

The study was approved by the Queensland Health Human Research Ethics Committee (Central Office). Potential participants were sent an invitation email on 23 October 2009 which included the study’s URL. The website presented potential participants with information about the survey and stated that participation would be completely voluntary, confidential, and anonymous (see Appendix B for a copy of the information presented).

Most of the survey was designed as an observational study of health professionals’ design preferences in relation to observation charts. However, each participant was also randomly assigned to evaluate one of nine existing charts at the end of the survey. The nine charts included the new ADDS chart designed to embody good chart design and eight charts of “good”, “average”, or “poor” quality from the usability evaluation (1). De-identified copies of the charts can be found in Appendix C. We chose to use a between-subjects design (rather than a within-subjects design where all participants would rate all nine charts) to minimise the amount of time participants would have to set aside to complete the survey.

2.4 Data Analysis

Data were exported from Checkbox on 7 December 2009. All analyses were conducted using SPSS Version 16.0.
3. Results

3.1 Participant characteristics

Three hundred and thirty-three participants completed the survey; their characteristics are listed in Table 1. The vast majority of the participants worked as nurses. The mean age of the current sample was comparable to that of the Australian nursing workforce (Australian $M = 43.7$ years) (19). However, males were over-represented in the current sample, compared with the general nursing workforce (Australia = 9.6%) (19).

The participants reported working in various geographical locations and in various areas within their institution. The survey used the Rural, Remote and Metropolitan Areas classification for participants’ place of work, which is not strictly comparable with the Australian Standard Geographical Classification used to describe the Australian nursing workforce (19, 20). However, the rank order of sites from metropolitan to very remote was in line with that of the general workforce. About a third of the participants reported working on wards, other work areas reported are listed in Table 1.

As stated previously, the majority of participants were nurses. Table 2 shows the career levels of the nurses in the current sample. In comparison to the Australian nursing workforce, educators and managers were over-represented, while clinical nurses were under-represented (19). Ten doctors also participated in the survey: one was a registrar, one was a visiting medical officer, three were staff specialists, and five were senior staff specialists.

3.2 Use of observation charts

The vast majority of participants reported using observation charts as part of their current role (see Figure 1). Out of those who reported using charts, most used charts more than once a day (see Figure 2) and recorded information in the charts (see Figure 3). As shown in Figure 4, about 73% of those who recorded information in charts did so more than once a day. Given the importance of using the observation chart in detecting patient deterioration, it is worrying that almost 18% of participants reported having had no training in the use of such charts (see Figure 5).

An Online Survey of Health Professionals’ Opinions Regarding Observation Charts

Figure 2: How frequently participants use observation charts, participants who reported not using observation charts (n = 50) were excluded.

Figure 3: Percentage of participants who record information in observation charts, participants who reported not using observation charts (n = 50) were excluded.
3.3 Understanding of abbreviations on observation charts

Figures 6 to 16 present the results for items that asked participants to nominate which term they first thought of when seeing a particular abbreviation. Most abbreviations were almost uniformly assigned the same meaning, e.g. “BP” was seen as standing for blood pressure. However, “SBP” and “LOC” both had sizeable groups of participants nominating alternative terms.

Figure 13: Participants' understanding of the abbreviation "Sats".
Figure 14: Participants' understanding of the abbreviation "Resp".

Figure 15: Participants' understanding of the abbreviation "HR".
3.4 Which abbreviations are rated as easiest to understand on observation charts

Figures 17 to 25 present participants’ preferred terms for 9 variables that commonly appear on observation charts. For some variables, there was a high level of agreement amongst the participants as to what they thought was easiest to understand, e.g. “BP” was most popular for blood pressure. For other variables, there was not a clearly preferred term, e.g. oxygen saturation.
Figure 18: Participants' preferred term for systolic blood pressure.

Figure 19: Participants' preferred term for pulse or heart rate.
Figure 20: Participants’ preferred term for respiratory rate.

Figure 21: Participants’ preferred term for oxygen saturation, note that the digit ‘2’ in ‘O2’ above was presented as subscript (i.e. ‘O₂’) in the survey.
Figure 22: Participants’ preferred term for oxygen delivery, note that the digit ‘2’ in ‘O2’ above was presented as subscript (i.e. ‘O$_2$’) in the survey.

Figure 23: Participants’ preferred term for temperature.
3.5 Preferences regarding recording vital signs and detecting deterioration on observation charts

Participants had a strong preference for plotting blood pressure and pulse together on the same graph, as opposed to plotting the two variables on separate graphs (see Table 3). Similarly, participants preferred to record both systolic and diastolic blood pressure, rather than only systolic
blood pressure. Participants also expressed the same preferences with regards to detecting patient deterioration.

*Note.* Response options were from 1 = *strongly disagree* to 5 = *strongly agree*, with a scale mid-point 3 = *neutral*.

Six formats for recording vital signs were presented to participants. As shown in Figure 26, participants preferred option 6 (*Plot the value on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality*), but a substantial proportion also preferred option 4 = (*Plot the value on a graph that has line(s) indicating physiological abnormality*). Participants also expressed the same preferences with regards to detecting patient deterioration (see Figure 27).
Figure 26: Participants’ preferences for how to record vital signs, where 1 = Write the value in a box; 2 = Plot the value on an otherwise ‘blank’ graph; 3 = Plot the value on a graph that has a line indicating physiological normality; 4 = Plot the value on a graph that has line(s) indicating physiological abnormality; 5 = Write the value in a box with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality; 6 = Plot the value on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality.

3.6 Participants’ evaluation of their institution’s current observation chart

Participants’ responses to 13 statements regarding their institution’s current observation chart are presented in Table 4. Together, the 13 items (with Items 3, 4, 6, 7, 9, and 10 reverse scored) formed a reliable scale (Cronbach’s $\alpha = 0.90$). Figure 27 shows the distribution of participants’ aggregated responses to the 13 items. The mean of the aggregated rating was 3.03 ($SD = 0.81$). Across the items, charts received the highest rating for being “easy to record vital signs on”, but received the worst rating for stating “how to respond when a patient’s vital signs are deteriorating”.

3.7 Participants’ evaluation of the 9 presented observation charts

Participants were randomly assigned to evaluate one of nine charts. The nine charts included charts of “good”, “average”, or “poor” quality. Charts 1, 2, and 3 were thought to be of “good” quality from a human factors perspective (a priori) (1). Charts 4, 5, and 6 were thought to be of “average” quality, that is, perhaps representative of the average observation chart used in Australia. Charts 7, 8, and 9 were thought to be of “poor” quality from a human factors perspective.

Participants’ responses to 13 statements regarding their assigned chart are presented in Table 5. The 13 items (with Items 3, 4, 6, 7, 9, and 10 reverse scored) formed a reliable scale (Cronbach’s α = 0.89). Table 6 shows participants’ aggregated responses to the 13 items for each of the nine charts.

A between-subjects one-way analysis of variance was conducted with chart type as the independent variable and the aggregated rating as the dependent variable. Levene’s test of homogeneity of variances indicated no significant differences in the variances of the nine groups, Levene’s statistic(8,299) = 0.38, p = 0.93.

There was a significant effect of chart type viewed on the aggregated rating, F(8,299) = 20.53, p < 0.001. Pairwise comparisons between charts were conducted using the Bonferroni method of correcting for multiple comparisons; results are listed in Table 7. The results of the pairwise comparisons show that Charts 7, 8, and 9 (collectively, the “poor” quality charts) were each rated as having a significantly poorer design compared to each of the other charts (collectively, the “average” and “good” quality charts). Therefore, there was partial support for our hypothesis that health professionals would rate the “good” charts as having better design, compared to the “average” and “poor” charts.

4. Discussion

Improving the recognition and management of patients who deteriorate whilst in hospital is a frequently cited priority for improving patient safety (2, 11). One way to improve the recognition and management of deteriorating patients is to improve the design of paper-based adult observation charts. The aim of the current study was to gauge the opinions of the population who actually use observation charts.

We recruited a large sample of health professionals (the vast majority of whom were nurses) to answer general questions about the design of observation charts and specific questions about nine observation charts. We found that most of our sample reported using charts more than once a day and that the majority recorded information in the charts more than once a day. Despite the participants reporting using observation charts daily and the importance of using patients’ vital signs to detect deterioration, only a minority (35%) reported receiving any formal training in the use of such charts.

In our initial heuristic analysis of observation charts, we found that the majority of charts included a large number of abbreviations (1). Furthermore, many charts included abbreviations that could potentially be misinterpreted (e.g. does “SBP” on a chart mean ‘systolic blood pressure’ or ‘standing blood pressure’?). In designing a user-friendly chart, it is important to assess whether the terms and abbreviations used in the chart are actually understood by chart users. A section of the online survey asked participants to nominate which term they first thought of when seeing a particular abbreviation. Most abbreviations were overwhelmingly assigned the same meaning, e.g. ‘blood pressure’ for the abbreviation “BP”. However, “SBP” and “LOC” both had substantial numbers of participants nominating different terms for the same abbreviation. Therefore, these two abbreviations should be avoided wherever possible in the design of observation charts.

Following on from gauging participants’ understanding of commonly used abbreviations, we asked participants to nominate their preferred terms for nine observations that commonly appear on charts. A user-friendly chart should incorporate users’ preferred terminology wherever possible (however, not when the preferred terminology is technically incorrect or potentially confusing). We found that there was a high level of agreement amongst the participants as to what they thought was easiest to understand for some variables, e.g. “BP” was most popular for blood pressure. For other variables, there was not a clearly preferred term, e.g. oxygen saturation.

Participants were also asked about their preferences for recording observations on charts. Interestingly, participants had a strong preference for plotting blood pressure and pulse together on the same graph (as opposed to plotting the two vital signs on separate graphs), and for plotting both systolic and diastolic blood pressure, rather than only systolic blood pressure. Participants also expressed the same preferences with regards to detecting patient deterioration. From a human factors point of view, plotting multiple vital signs (e.g. systolic blood pressure, diastolic blood pressure, and pulse) on the same graph is seen as potentially problematic, in that the display is likely to become cluttered, and patient deterioration on one vital sign could be obscured by observations for one or both of the other vital signs. The final item in this section of the survey presented six
formats for recording vital signs. For both recording observations and detecting patient deterioration, participants preferred option 6 *(Plot the value on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality).* On this item, participants’ preference was in line with what a human factors approach would recommend (i.e. a chart with a colour-coded track and trigger system).

In the final sections of the survey, participants were first asked to respond to 13 statements regarding their institution’s current observation chart, and then to respond to the same 13 statements for one of nine observation charts. The nine observation charts included the new observation chart and eight observation charts of “good”, “average”, or “poor” design quality, according to the usability evaluation. It was hypothesised that health professionals would rate the “good” charts as having better design, compared to the “average” and “poor” charts.

Participants’ mean aggregated rating across the 13 items for their institution’s current observation chart was close to the scale’s mid-point, 3 = neutral. For the assigned charts, participants’ mean aggregated rating varied from 3.43 (tending to agree with positive statements about the chart) for Chart 3 to 2.12 (tending to disagree with positive statements about the chart) for Chart 9. Indeed, we found that there was a statistically significant effect of chart type on the aggregated rating. Charts 7, 8, and 9 (collectively, the a priori “poor” quality charts) were each rated as having a significantly poorer design compared to each of the other charts (collectively, the a priori “average” and “good” quality charts). Therefore, there was partial support for our hypothesis that health professionals would rate the “good” charts as having better design, compared to the “average” and “poor” charts.

As a result of collecting data regarding the preferences of participants in the online survey, we made some changes to the terms used in new ADDS chart. We changed ‘O₂ Delivery’ to ‘O₂ Flow Rate’, as ‘O₂ Flow Rate’ was the second most popular term after ‘O₂ LPM’ for that observation (we did not include ‘O₂ LPM’ as this would introduce a new and unnecessary abbreviation into the chart). We changed ‘Urine for 4 Hours’ to ‘4 Hour Urine Output’ as it was the most popular term for that vital sign. We also changed ‘Pulse’ to ‘Heart Rate’ as the combined preferences for ‘Heart Rate’, ‘HR’, and ‘H.R.’ eclipsed those for ‘Pulse’ and ‘P’ (we did not include the single most popular term, ‘HR’, as this would introduce an unnecessary abbreviation into the chart). We kept other terms unchanged on the ADDS chart as we generally preferred using the full word over more popular abbreviations (i.e. ‘Temperature’, not ‘Temp’).

Responses to other sections of the online survey also suggested that we not modify the overall design of the ADDS chart at this stage. First, participants expressed a preference for “plotting the value [for a vital sign] on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for abnormality” for both recording observations and detecting patient deterioration. All of the ADDS chart’s vital signs are to be plotted in this manner (except blood pressure, for which users have to consult a look-up table). Second, participants’ aggregated rating for the ADDS chart was no worse than that of any other chart (and significantly better than Charts 7, 8 and 9), even though the ADDS chart could be argued to be radically different from many existing observation charts that participants may be familiar with.
The online survey served two main purposes. First, it collected quantitative data on health professionals’ general preferences regarding aspects of the design of observation charts. This information informed the design of the ADDS chart and could also be used by other chart designers to produce more user-friendly hospital charts. Second, the online survey enabled health professionals to rate the design of the ADDS chart as well as eight existing charts of varying quality. Overall, health professionals agreed with our human factors-based rating with regards to the “poor” quality charts. However, the health professionals did not differentiate between the “average” and “good” quality charts in their ratings.

Appendix A: Online Survey Items

**Questions about your background:**

What is your occupation?

- Nurse
- Doctor
- Other health professional: 

Which of the following best describes your nursing role?

- Enrolled Nurse
- Nursing Assistant
- Registered Nurse
- Clinical Nurse
- Nurse Unit Manager
- Nurse Educator
- Nursing Director
- Nurse Practitioner
- Other: 

Which of the following best describes your medical role?

- [ ] Post-graduate year 1 (Intern)
- [ ] Post-graduate year 2 and not in an accredited training program
- [ ] Post-graduate year 3 and not in an accredited training program
- [ ] Post-graduate year 4+ and not in an accredited training program
- [ ] Post-graduate and in an accredited training program
- [ ] Hospitalist
- [ ] Career Medical Officer
- [ ] Senior Medical Officer
- [ ] Visiting Medical Officer
- [ ] Staff Specialist
- [ ] Senior Staff Specialist
- [ ] Other: 

How many years have you been registered? [ ]

What is the postcode of your institution or place of work? [ ]

In what type of area is your institution located? Response options are modelled on the RRMA (Rural, Remote and Metropolitan Areas) classification

- [ ] Capital City
- [ ] Other Metropolitan Centres (urban centre population > 100,000)
- [ ] Large Rural Centres (urban centre population 25,000–99,999)
- [ ] Small Rural Centres (urban centre population 10,000–24,999)
- [ ] Other Rural Areas (urban centre population < 10,000)
- [ ] Remote Centres (urban centre population > 5,000)
- [ ] Other Remote Areas (urban centre population < 5,000)
- [ ] Do not know
At your institution, where do you spend the greatest proportion of your time working?

- Ward
- Emergency
- Intensive Care Unit
- Theatre
- Outpatient Clinic
- Other: 

Your sex:

- Female
- Male

Your age in years: 

Do you wear glasses or contact lenses in order to read?

- Yes
- No

Are you colour-blind?

- Yes
- No

What type of colour-blindness do you have (for example, red-green)? 

Does your colour-blindness impact on your work?

- Yes
- No
The following questions are about the design and use of General Observation Charts. All responses are completely anonymous. Please answer the following questions as honestly and accurately as possible. There are no right or wrong answers.

The first few questions are about your current use of General Observation Charts.

Do you use Observation Charts as part of your current role?
- [ ] Yes
- [ ] No

What training have you received in the use of Observation Charts? Select all that apply:
- [ ] None
- [ ] Read the instructions
- [ ] Informal (for example, by co-worker)
- [ ] Formal (for example, in-service or workshop)
- [ ] Other: __________________________

How frequently do you use Observation Charts?
- [ ] More than once a day
- [ ] Once a day
- [ ] More than once a week, but less than once a day
- [ ] Once a week
- [ ] More than once a month, but less than once a week
- [ ] Once a month
- [ ] Less than once a month
Do you **record information** in Observation Charts as part of your current role?

- [ ] Yes
- [ ] No

How frequently do you **record information** in Observation Charts?

- [ ] More than once a day
- [ ] Once a day
- [ ] More than once a week, but less than once a day
- [ ] Once a week
- [ ] More than once a month, but less than once a week
- [ ] Once a month
- [ ] Less than once a month

The next few questions are about abbreviations sometimes found on Observation Charts. These questions assess how easy to understand the abbreviations are, not your level of medical knowledge.

What do you first think of when you see “P” on an Observation Chart?

- [ ] Patient
- [ ] Pain
- [ ] Pulse
- [ ] Other: ____________

What do you first think of when you see “R” on an Observation Chart?

- [ ] Respiratory Rate
- [ ] Responsibility
- [ ] Responsive
- [ ] Other: ____________
What do you first think of when you see “T” on an Observation Chart?

☐ Time
☐ Temperature
☐ Total
☐ Other: 

What do you first think of when you see “LOC” on an Observation Chart?

☐ Loss of consciousness
☐ Level of care
☐ Level of consciousness
☐ Other: 

What do you first think of when you see “Temp” on an Observation Chart?

☐ Temporary
☐ Temperature
☐ Template
☐ Other: 

What do you first think of when you see “BP” on an Observation Chart?

☐ Blood pressure
☐ Body part
☐ Beats per...
☐ Other: 

What do you first think of when you see “RR” on an Observation Chart?

☐ Relative risk
☐ Recovery room
☐ Respiratory rate
☐ Other: 

An Online Survey of Health Professionals’ Opinions Regarding Observation Charts

46
What do you first think of when you see “Sats” on an Observation Chart?

- Satisfaction
- Oxygen saturation
- Standard Adult Test Score
- Other: 

What do you first think of when you see “Resp” on an Observation Chart?

- Respiratory rate
- Responsibility
- Responsive
- Other: 

What do you first think of when you see “HR” on an Observation Chart?

- Hour
- Human Resources
- Heart Rate
- Other: 

What do you first think of when you see “SBP” on an Observation Chart?

- Standing Blood Pressure
- Systolic Blood Pressure
- Spontaneous Bacterial Peritonitis
- Other: 

An Online Survey of Health Professionals’ Opinions Regarding Observation Charts
The next few questions are about which terms you think are the easiest for the average nurse to understand.

For blood pressure, which term do you think is the easiest for the average nurse to understand? Select one of the following:

- Blood Pressure
- B.P.
- BP

Please enter any comments you would like to make about the terms for blood pressure:

For systolic blood pressure, which term do you think is the easiest for the average nurse to understand? Select one of the following:

- Systolic Blood Pressure
- Sys Blood Pressure
- Systolic BP
- Sys BP
- S.B.P.
- S/BP
- SBP

Please enter any comments you would like to make about the terms for systolic blood pressure:
An Online Survey of Health Professionals’ Opinions Regarding Observation Charts

For pulse or heart rate (beats per minute), which term do you think is the easiest for the average nurse to understand? Select one of the following:

- [ ] Heart Rate
- [ ] Pulse
- [ ] HR
- [ ] H.R.
- [ ] P

Please enter any comments you would like to make about the terms for pulse or heart rate:

[Box for comments]

For respiratory rate (breaths per minute), which term do you think is the easiest for the average nurse to understand? Select one of the following:

- [ ] Respiratory Rate
- [ ] Resp Rate
- [ ] Respirations
- [ ] Respiration
- [ ] Resps
- [ ] Resp
- [ ] RR
- [ ] R.R.
- [ ] R

Please enter any comments you would like to make about the terms for respiratory rate:

[Box for comments]
For oxygen saturation, which term do you think is the easiest for the average nurse to understand? Select one of the following:

- Oxygen Saturation (SaO₂)
- Oxygen Saturation (SpO₂)
- Oxygen Saturation
- Oxygen – Saturation %
- O₂ Saturation %
- O₂ Saturation
- Saturation
- Sats (SpO₂)
- O₂Sat
- O₂Sat %
- O₂ sat
- Sat O₂
- SpO₂ %
- SpO₂ Sats
- SpO₂ Sats %
- SpO₂
- SaO₂

Please enter any comments you would like to make about the terms for oxygen saturation:
For the rate of oxygen delivery, which term do you think is the easiest for the average nurse to understand? Select one of the following:

- Rate of oxygen delivery
- Oxygen delivery
- O₂ delivery
- Oxygen delivered
- O₂ delivered
- Oxygen therapy
- O₂ therapy
- Oxygen flow rate
- O₂ flow rate
- Oxygen rate
- O₂ rate
- Oxygen
- O₂
- Litres of O₂
- O₂ LPM

Please enter any comments you would like to make about the terms for rate of oxygen delivery:
For temperature, which term do you think is the easiest for the average nurse to understand? Select one of the following:

- Temperature
- Temp
- T

Please enter any comments you would like to make about the terms for temperature:

For urine output (urine in millilitres per 4 hours), which term do you think is the easiest for the average nurse to understand? Select one of the following:

- 4 hour Urine Output
- Urine for 4 hours
- Urinary output
- Urine output
- Output urine
- Urine

Please enter any comments you would like to make about the terms for urine output:
For level of consciousness, which term do you think is the easiest for the average nurse to understand? Select one of the following:

- [ ] Level of Consciousness
- [ ] Consciousness
- [ ] Conscious Level
- [ ] Level of Alertness
- [ ] Sedation Score
- [ ] Alertness
- [ ] Sedation
- [ ] LOC

Please enter any comments you would like to make about the terms for level of consciousness:
Next, we are going to be asking you first about recording vital signs on Observation Charts (on this page) and we will then ask you the same questions about detecting patient deterioration using Observation Charts on the next page.

The questions on this page are about recording vital signs on Observation Charts.

When recording vital signs (e.g. pulse) I would prefer to:

1. Write the value in a box

   Pulse
   74  83  70  76  68  80  82  95  86  97  90  89  118  122  111  102  107  97

2. Plot the value on an otherwise ‘blank’ graph

3. Plot the value on a graph that has a line indicating physiological normality

4. Plot the value on a graph that has line(s) indicating physiological abnormality
Write the value in a box with graded colouring, where the colours correspond to a scoring system or graded responses for physiological abnormality

Plot the value on a graph with graded colouring, where the colours correspond to a scoring system or graded responses for physiological abnormality
I would prefer to plot blood pressure and pulse together on the same graph (for example, Image 1 below), rather than on separate graphs (for example, Image 2 below). Please indicate your level of agreement with this statement:

<table>
<thead>
<tr>
<th>Strongly disagree</th>
<th>Neutral</th>
<th>Strongly agree</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="https://via.placeholder.com/150" alt="Image 1" /></td>
<td><img src="https://via.placeholder.com/150" alt="Image 2" /></td>
<td></td>
</tr>
</tbody>
</table>

**Image 1**: An example of blood pressure and pulse plotted together on the same graph
Image 2: An example of blood pressure and pulse plotted on separate graphs
I would prefer to record both systolic and diastolic blood pressure together (for example, Image 3 below), rather than only systolic blood pressure (for example, Image 4 below). Please indicate your level of agreement with this statement:

<table>
<thead>
<tr>
<th>Strongly disagree</th>
<th>Neutral</th>
<th>Strongly agree</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td></td>
</tr>
</tbody>
</table>

Image 3: An example of recording both systolic and diastolic blood pressure

Image 4: An example of recording only systolic blood pressure
The questions on this page are about detecting patient deterioration using Observation Charts.

I would find it easier to detect patient deterioration when vital signs (e.g. pulse) are presented as:

- Write the value in a box

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

- Plot the value on an otherwise ‘blank’ graph

![Graph](image)

- Plot the value on a graph that has a line indicating physiological normality

![Graph](image)

- Plot the value on a graph that has line(s) indicating physiological abnormality

![Graph](image)

- Write the value in a box with graded colouring, where the colours correspond to a scoring system or graded responses for physiological abnormality

![Graph](image)
I would find it easier to detect patient deterioration when blood pressure and pulse are together on the same graph (for example, Image 1 below), rather than on separate graphs (for example, Image 2 below). Please indicate your level of agreement with this statement:

Strongly disagree  Neutral  Strongly agree

Image 1: An example of blood pressure and pulse plotted together on the same graph
Image 2: An example of blood pressure and pulse plotted on separate graphs
I would find it easier to detect patient deterioration when both systolic and diastolic blood pressure are recorded together (for example, Image 3 below), rather than only systolic blood pressure (for example, Image 4 below). Please indicate your level of agreement with this statement:

<table>
<thead>
<tr>
<th>Strongly disagree</th>
<th>Neutral</th>
<th>Strongly agree</th>

End of survey questions.

Please enter your email address if you would like to enter the prize draw to win a new Apple iPhone. Your survey responses and your email address will be stored separately to maintain your anonymity.

I would like to receive a summary of the survey’s findings sent via email.

☐ Yes
☐ No

Thank you for taking part in the survey. You have been entered in the prize draw to win a new Apple iPhone.
Appendix B: Participant Information About the Online Survey

An Online Survey of Health Professionals’ Opinions of Adult General Observation Charts

Participant Information (scroll down)

You are invited to take part in this online survey of health professionals. This survey aims to gauge the opinions of health professionals regarding the design and use of adult general observation charts. This survey is part of a larger project examining the design and use of observation charts to identify and respond to patient deterioration.

Win a new iPhone!

If you complete our survey, you will be eligible to enter a prize draw to win a new Apple iPhone. All you have to do is enter your email address after the end of the survey. Your survey responses and your email address will be stored separately to maintain your anonymity.

What does participation in this survey involve?

We would like you to complete a 15 to 20 minute survey. You will need to complete the survey in one sitting. The survey program does not allow you to save your incomplete responses to return to at a later time.

You will be asked questions about your professional background and about various aspects of observation chart design. There will be an opportunity for you to make open-ended comments if you would like to.

What are the possible benefits?

This survey is part of a larger project examining the design and use of observation charts. Developing a more user-friendly observation chart is likely to reduce the number of serious adverse events associated with undetected patient deterioration.

How will I be informed of the findings of this survey?

A summary of the project’s findings will be sent to you via an email if you enter your email address after the end of the survey. Your responses and your email address will be stored separately to maintain your anonymity.

What will happen to information generated in this survey?

Survey results will be communicated in a report to the Australian Commission on Safety and Quality in Health Care. It is intended that survey results also be published in a peer-reviewed scientific journal.

Is this research project approved?

This study has been reviewed and approved by the Queensland Health Central Office Human Research Ethics Committee. Should you wish to discuss the study with someone not directly involved, in particular in relation to matters concerning policies, information about the conduct of the study or your rights as a participant, or should you wish to make an independent complaint, you can contact the Coordinator, Human Research Ethics Committee (3234 0034 or Enable JavaScript to view Email Address)

Consenting to participate

Participation in this survey is completely voluntary and confidential. Information supplied by you will be completely identifiable. If you decide to take part and later change your mind, you are free to withdraw from the survey at any time.

By clicking "I agree" you are telling us that you:

- Understand what you have read
- Consent to take part in the survey
An Online Survey of Health Professionals’ Opinions Regarding Observation Charts

Thank you,

The Research Team

Research Team:

Assoc. Professor Marcus Watson
Principal Investigator
Skills Development Centre

Dr Mark Horowill
Senior Investigator
University of Queensland

Queensland Health Skills Development Centre
Queensland Health Patient Safety Centre
The University of Queensland School of Psychology
Australian Commission on Safety and Quality in Health Care

*Terms and Conditions

1. Introduction: The Online Survey of Health Professionals’ Opinions of Adult General Observation Charts Promotion (“Promotion”) is conducted by The University of Queensland (“UQ”) under the Charitable and Non-Profit Gaming Act 1999 (Qld).

The winner of the prize will be selected in a random draw from all eligible entries received by the School of Psychology. Odds of winning will depend on the number of eligible entries received. Please note that at least 100 eligible responses are expected. At least 1,000 people have been invited to take part in this online survey with an estimated 15% response rate.

2. Timing: The Promotion will take place from the 19th October 2009 to the 30th November 2009 (“Promotion Period”).

3. Closing date: The Promotion closes at 5.00pm on the 30th November 2009 (“Closing Date”).

4. Eligibility: All prizes offered as part of the Promotion are open to all individuals who:
   a. are Australian residents; and
   b. have completed and submitted the Online Survey of Health Professionals’ Opinions of Adult General Observation Charts.

5. How to enter: Eligible persons must have completed Online Survey of Health Professionals’ Opinions of Adult General Observation Charts, with a valid email address.

Entries received before 5pm on 30th November 2009 will be eligible to enter the prize draw. Only one entry per person will be registered and included in the draw for the prize.

6. Selection of winner: On 1st December 2009, UQ will randomly select a winner from all eligible entries received during the Promotion Period.

7. Notification of the winner: The winner will be notified via email within 48 hours of the prize being drawn. The winner must sign and return to the School of Psychology, a Personal Payment Details form to claim the Prize. If the Prize is not claimed by 31st January 2010, the Prize will be forfeited and the winner’s entitlement will lapse.

8. Prize: Apple iPhone 3G 16GB, RRP A$879.

9. Data Collection: Information provided in the Online Survey of Health Professionals’ Opinions of Adult General Observation Charts will be used for the purpose of:
   a. research into the adult general observation charts;
   b. selecting a winner for this Promotion; and

I agree to participate in this project.

I disagree. I DO NOT agree to participate in this project.

**MET Criteria:**

- All respiratory & cardiac arrest
- Threatened Airway, RR < 5 or > 36
- Systolic BP < 90
- Sudden fall in level of consciousness, fall of GCS > 2, repeated or prolonged seizures
- Any patient you are seriously worried about that does not fit the above criteria

- Blood Pressure (mmHg): SBP is lower
- Blood Pressure (mmHg): DBP is higher
- Vital Signs: Normal
- Vital Signs: Abnormal

Legend:
- Red: Paediatric Review
- Yellow: Clinical Review
Clinical Review Criteria

- SpO₂ 90-95% and/or increase in Oxygen (O₂) requirement
- Respiratory rate 5-10 breaths per minute or 25-30 breaths per minute
- Pulse rate 60-100 or 120-140 beats per minute
- Systolic BP 90-160 or 200-240 mmHg
- Poor peripheral circulation
- Urine output <200 mL over 8 hours; anuria or failure to void in 24 hours
- Greater than expected drainage fluid loss
- New, increasing or uncontrolled pain (including chest pain)
- BGL <4 mmol/L
- Arterial Blood Gas: PaO₂ <60, PaCO₂ >60, pH <7.2, BE < -5
- Excess or increasing blood loss

If any of the above criteria are met you MUST call for a Clinical Review (refer to your local protocol) and:

1. Inform the nurse in charge of the shift
2. Conduct and record observations as indicated by patient condition but at least within 30 minutes
3. Document action taken, in the progress notes
4. If clinical review not attended
   a. Observations within the yellow zone – Repeat Clinical Review Call
   b. Observations within red zone – Escalate to Rapid Response Call

Rapid Response Criteria

- ALL respiratory and cardiac arrests
- Airway obstruction or stridor
- Seizures
- SpO₂ <90% and/or increase in Oxygen (O₂) requirement
- Respiratory rate <5 or >30 breaths per minute
- Pulse rate <60 or >140 beats per minute
- Systolic BP <90 or >240 mmHg
- Sudden decrease in level of consciousness or unresponsive to command
- Serious concern by any staff member

If any of the above criteria are met you MUST activate your local Rapid Response (refer to local protocol) and:

1. Inform the nurse in charge of the shift
2. Conduct and record observations as indicated by patient condition but at least within 30 minutes
3. Document action taken, in the progress notes

IF THE PATIENT HAS BEEN MADE ‘NOT FOR CPR’ THE ABOVE TRIGGERS MAY NOT APPLY

DOCUMENTATION – IN PROGRESS NOTES
1. Name and position
2. Date and Time
3. Action taken: including how patient was managed, escalation process, treatment given and outcome (patient location, transferred to diagnostic services or higher level / acute care)

**Observation Chart**

- All general observations from admission to discharge other than those at end of shift.
- Glasgow Coma Scale for Critical Care units.
- All observations for patients receiving I.V. or continuous saline solution.

**Documentation**

- Documentation of all observations, wounds, etc.
- Documentation of drugs, lab observations, etc.

**Administration of Drugs**

- Document total amount of drug in milligrams/hour.
- Document total amount of drug in milligrams/kg.
- Document total amount of drug in milligrams/day.
- Document total amount of drug in milligrams/week.
- Document total amount of drug in milligrams/month.
- Document total amount of drug in milligrams/year.

**Documentation of Injections**

- Document total amount of drug in milligrams/hour.
- Document total amount of drug in milligrams/kg.
- Document total amount of drug in milligrams/day.
- Document total amount of drug in milligrams/week.
- Document total amount of drug in milligrams/month.
- Document total amount of drug in milligrams/year.

**Documentation of Other Observations**

- Document total amount of drug in milligrams/hour.
- Document total amount of drug in milligrams/kg.
- Document total amount of drug in milligrams/day.
- Document total amount of drug in milligrams/week.
- Document total amount of drug in milligrams/month.
- Document total amount of drug in milligrams/year.

**Documentation of Drug Administration**

- Document total amount of drug in milligrams/hour.
- Document total amount of drug in milligrams/kg.
- Document total amount of drug in milligrams/day.
- Document total amount of drug in milligrams/week.
- Document total amount of drug in milligrams/month.
- Document total amount of drug in milligrams/year.
