ABSTRACT

Introduction: Electronic cigarette (e-cigarette) awareness, trial of e-cigarettes in the past 12 months, source and perceptions of safety and effectiveness was assessed within a disadvantaged sample of adult Australian smokers receiving welfare aid.

Methods: A cross-sectional survey was administered to clients who smoke at two community service organisations in New South Wales, Australia from October 2013 to July 2014. E-cigarette awareness, trial in past 12 months, sources of e-cigarettes and perceptions of the safety and effectiveness of e-cigarettes to help people quit were assessed along with sociodemographic and smoking-related variables.

Results: In total, 369 participants completed the survey (77% response rate). Awareness and trial of e-cigarettes were reported by 77% (n = 283) and 35% (n = 103) of the sample respectively. E-cigarettes were most commonly obtained from friends/strangers followed by tobacco shops (tobacconists). Trying e-cigarettes in the past 12 months was significantly associated with positive perceptions of their safety (OR = 1.8, CI = 1, 3.1) and effectiveness (OR = 1.9, CI = 1.1, 3.2). Motivation to quit tobacco smoking was also significantly positively associated with positive perceptions of e-cigarette safety (OR = 1.2, CI = 1.1, 1.4) and effectiveness (OR = 1.2, CI = 1.0, 1.3).

Conclusions: Rates of awareness and trial of e-cigarettes within a disadvantaged sample of Australian smokers are comparable to rates found within representative samples of the general Australian population. Previously trying e-cigarettes and higher levels of motivation to quit were associated with more positive perceptions of e-cigarette safety and effectiveness.

247

Implications:

This study provides novel information regarding the awareness, perceptions and trial of e-cigarettes in a sample of smokers experiencing multiple forms of socioeconomic disadvantage.
INTRODUCTION

In high income countries, the highest prevalence of smoking is concentrated in the most disadvantaged groups in society. Rates of smoking are highest amongst people with the lowest level of income (25% - 30%) \(^1\); people with a mental illness (32%) \(^2\); people with alcohol and other substance use disorders \(^3\); people who are homeless (73%) \(^4\); Indigenous people (31% - 52%) \(^5,7\); and prisoners (78% - 84%) \(^8,9\). Individuals within these groups often experience multiple forms of disadvantage, for example, people who are homeless are more likely to experience mental illness \(^10\). These groups have been identified as priority targets for smoking cessation research \(^11\), recognising the need for novel approaches.

Electronic cigarettes (also known as electronic nicotine delivery systems or e-cigarettes) have recently emerged as potential smoking cessation aids for smokers. E-cigarettes deliver an aerosol usually consisting of a carrier solution (typically propylene glycol and/or vegetable glycerol), flavourings and often, but not always, nicotine. In Australia, possession and/or use of an e-cigarette containing nicotine without a prescription from a medical practitioner is illegal in all states \(^12\). It is legal to possess and use e-cigarettes that do not contain nicotine, however sale may be unlawful in some Australian states \(^12\). This is in contrast with the USA and many parts of Europe where there are relatively few restrictions placed on marketing and purchase of e-cigarettes with or without nicotine \(^13\).

The two strongest arguments for the use and regulated promotion of e-cigarettes within the tobacco control research field are that e-cigarettes represent a safer alternative to tobacco cigarettes and can be used to aid current smokers to quit smoking. Two trials have demonstrated that using an e-cigarette containing nicotine is associated with increased likelihood of cessation at six months follow up compared to using e-cigarettes without nicotine \(^14\). However the safety and effectiveness of e-cigarettes have not yet been established \(^14,15\). Another argument is to promote the long-term use of e-
cigarettes as a method of harm reduction for smokers unable to quit, such as those from disadvantaged groups who are heavily nicotine dependent and have made numerous unsuccessful quit attempts. Awareness and use of e-cigarettes appears to be increasing over time in both the international literature and in Australia. Surveys assessing smokers and ex-smokers awareness of e-cigarettes in the UK, US, Australia and Canada found an overall awareness of 46% in 2013. In Australia and the UK, awareness of e-cigarettes had increased to 91% in 2014. Estimates of ever use ranged from 8% in 2013 across smokers and smokers in the UK, US, Australia and Canada to 35% in Australia and the UK in 2014. In 2014, estimates of current e-cigarette use in the general population range from 1% to 6%. Levels of awareness and ever use in current and former smokers are generally lower in Australia compared to the UK and USA. This may be due in part to the differences in regulations covering e-cigarettes between these countries and Australia.

To date, only two US-based studies exploring awareness and use of e-cigarettes within disadvantaged groups have been published. In a sample of opioid dependent smokers, levels of e-cigarette awareness (99%), ever use (73%) and use in the past 30 days (33%) were higher than levels found within the general US population. In a national probability sample of smokers and non-smokers, those reporting a mental health condition were significantly more likely to have tried e-cigarettes (15%) than those without (7%). Levels of current use in this probability sample were higher for those with a mental health condition (9%) than those without (5%), however this difference was not significant.

Data concerning e-cigarette use in disadvantaged groups in Australia are lacking. Comparing awareness, use and attitudes across countries may provide insight on the impact of different regulatory environments. If e-cigarettes develop a stronger evidence base as a smoking cessation aid or harm reduction strategy, information about awareness, use and perceptions of e-cigarettes is needed to shape policy. A better understanding of the awareness, use and perceptions of e-cigarettes within a highly socioeconomically disadvantaged group of smokers will also help inform the current limited research agenda on smoking and disadvantaged groups.

**Aims**

Within a sample of socioeconomically disadvantaged smokers, this study aims to examine:
a) the percentage of participants who i) have ever heard about e-cigarettes and ii) have tried e-cigarettes in the past 12 months;
b) the most common ways e-cigarettes are obtained;
c) perceptions of e-cigarette safety, cost, and effectiveness as an aid to quit;
d) whether perceptions of e-cigarettes are associated with use.

METHODS

Study design

A cross sectional survey was conducted at two non-government community service organisations (CSO) in New South Wales, Australia, from October 2013 to July 2014. The study aimed to sample priority groups with high smoking prevalence rates including people who are homeless, unemployed, with mental illness, and of Aboriginal and/or Torres Strait Islander background. Although these groups are hard to reach, recruitment via CSOs represents an effective mechanism for obtaining a representative sample. Both CSO sites provided financial and material assistance to clients experiencing financial hardship.

Participants

Eligible participants were 1) clients of the CSO, 2) aged 18 years or older, 3) not under the influence of alcohol or other drugs at time of recruitment, 4) not too distressed to complete the survey and 5) current daily or occasional smokers. Self-reported smoking status was assessed using the following two items 1) “Do you currently smoke tobacco products?” with the following response options a) Yes daily b) Yes at least once a week c) Yes but less often than once a week and d) No, not at all and 2) “Have you smoked at least 100 cigarettes or a similar amount of smoking in your life?” a) Yes b) No or c) Not sure. Current smokers were defined as self-reported daily or occasional smokers who had smoked at least 100 cigarettes in their lifetime.

Procedure

CSO staff informed all clients about a health survey being conducted at the organisation and clients were asked to approach the Research Assistant (RA) for more information. RAs provided an Information Statement and assessed client eligibility. Survey completion was taken as consent. The survey was administered via a touchscreen computer. The RA provided assistance in completing the
survey where necessary. The survey included 40 items in total and the mean completion time was 16.2 minutes (ranged from 9.2 – 21.3 minutes). Only those data relating to e-cigarettes are presented in this paper. Participants received a $10 grocery card gift voucher as reimbursement for completing the survey. Ethics approval was granted by the University of Newcastle’s Human Research Ethics committee.

**Measures:**

**Sociodemographic variables:**

Age, gender, Aboriginal and/or Torres Strait Islander (Indigenous) status, education, housing status, weekly net income, and source of income were assessed.

**E-cigarette awareness, ever use, source and perceptions:**

Participants were presented with an image of an e-cigarette (Supplementary file 1) along with a brief description of e-cigarettes before they were presented with e-cigarette questions. The description read: “The following questions are about electronic cigarettes or e-cigarettes. An e-cigarette (like the one shown on the left here) uses a battery and may also light up or have smoke (vapour) coming from it like a real cigarette”. To assess awareness, participants were asked “Before now, have you ever heard of electronic cigarettes or e-cigarettes?” and to assess use in the past 12 months they were asked “In the last 12 months, have you ever tried electronic cigarettes or e-cigarettes, even just one time?”. Participants who reported trying e-cigarettes in the past 12 months were asked from where they had obtained e-cigarettes with response options: a) internet/online; b) tobacco shop (tobacconist); c) friend or stranger; d) while travelling overseas or e) other. Participants could select multiple responses. Perceptions of e-cigarettes were assessed on a Likert-type scale from one (strongly disagree) to five (strongly agree) with the following statements “E-cigarettes can help people quit smoking tobacco”, “I would switch to e-cigarettes if they were cheaper than tobacco cigarettes”, “E-cigarettes are safer to use than tobacco cigarettes” and “I would give e-cigarettes a go to help me quit smoking”.

**Additional covariates**

Quit attempts in the past 12 months were assessed by asking all current smokers “Have you made a serious attempt to quit smoking in the last 12 months? By serious attempt I mean you decided
that you would try to make sure you never smoked again (Yes/No)?” \(^{23}\). Motivation to quit was assessed on a 10 point Likert scale where 1 = very low, 10 = very high \(^{24}\). Nicotine dependence was assessed using the two-item Heaviness of Smoking Index (HSI) with higher scores indicating higher levels of nicotine dependence \(^{25}\). Self-efficacy was assessed using the following: “If you decided to give up smoking completely in the next 6 months, how sure are you that you would succeed?” 1) Not at all sure, 2) Slightly sure, 3) Moderately sure, 4) Very sure, or 5) Extremely sure \(^{23}\).

**Data analysis:**

Percentages and 95% confidence intervals were calculated for the number of respondents indicating they were aware of electronic cigarettes and those who had responded ever trying e-cigarettes. Chi square analysis was carried out to investigate differences in the proportion of participants strongly agreeing or agreeing to the four statements assessing perceptions of e-cigarettes. Binary logistic regression was used to examine whether having tried e-cigarettes in the past 12 months was associated with agreement that e-cigarettes can assist with quitting and that e-cigarettes are safer, adjusting for demographic and smoking characteristics.

The variables included in logistic regression models were: e-cigarette use in past 12 months, age, gender, HSI, Indigenous status, highest level of education, motivation to quit, quit attempt in the last 12 months and self-efficacy. As two sites were used as recruitment centres for this survey, recruitment site was included as a covariate to control for any differences by centre. Collinearity of variables was checked using Variance Inflation Factors (VIFS) and linearity assumption for continuous variables and the (log) outcome were examined. Crude and adjusted odds ratios, with 95% confidence intervals and p-values were calculated for variables in the model. Consideration was made at each step that the removal of each non-significant variable did not negatively affect either the fit of the model (measured by significant change in likelihood ratio test or more than four point increase in Akaike Information Criterion (AIC) or change the estimates for remaining variables by no more than 10%. SAS 9.4 (SAS Institute Inc., Cary, NC, USA) was used for all analyses.

**RESULTS**
Response rates

Of the 606 clients attending the two centres during the study period, 478 (78%) clients were eligible to take part and invited to see the RA for more information about the study. Reasons for ineligibility included being a non-smoker (n=96), being under the influence of alcohol or other drugs (n = 5), distress (n =3 ), and being aged under 18 years (n = 5). Of eligible clients, 369 (77%) individuals consented and gave complete survey data.

Sociodemographic characteristics of the sample

The sample of participants was highly socioeconomically disadvantaged (see Table 1). Individuals self-reporting as Aboriginal and/or Torres Strait Islander made up 21% (n = 60) of the sample, compared to 2.2% of the population in New South Wales. The sample displayed exceptionally low income with 71% (n = 261) reporting income well below the Australian single-person ‘poverty line’ of $500 per week and 91% (n = 337) dependent on government benefits as their main source of income.

Awareness, past 12 month use and source of obtaining e-cigarettes:

Seventy-seven percent of the sample (n = 283) said they had heard of e-cigarettes and of those individuals, 36% (n = 103) had used e-cigarettes at least once in the past 12 months (see Table 2). The most common sources for obtaining e-cigarettes were from a friend or stranger (52%, n = 53) followed by from a tobacco shop (40%, n = 41). The “other” response category included obtaining e-cigarettes from the internet and overseas (9%, n = 18).

Perceptions of e-cigarettes:

Participant perceptions of e-cigarettes are reported in Table 3. Significantly higher proportions of participants who had tried e-cigarettes at least once in the past 12 months either agreed or strongly agreed that e-cigarettes are safer to use than tobacco cigarettes (58% versus 44%, p = .03) and that e-cigarettes can help people quit smoking (51% versus 34%, p <.01) compared to those who had not tried e-cigarettes within the past 12 months. No significant difference was found between those who had tried e-cigarettes and those who had not tried e-cigarettes regarding whether they would use e-cigarettes if they were cheaper than tobacco cigarettes or the intention to use cigarettes in order to quit smoking.
After adjusting for demographic and smoking characteristics, the odds of agreeing that e-cigarettes can help people quit smoking tobacco were 1.9 times higher in participants who had tried e-cigarettes, compared to those who had not (CI = 1.1, 3.2). Odds of agreeing that e-cigarettes can help people quit smoking were also higher for those who had higher levels of motivation to quit smoking (OR = 1.2, CI = 1.0, 1.3). All other variables were non-significant (Table 4).

The odds of agreeing with the statement that e-cigarettes are safer to use than tobacco cigarettes were 1.8 times higher in participants who had tried e-cigarettes, compared to those who had not (CI = 1.0, 3.1). Females (OR = 2.0, CI = 1.2, 3.3) and participants with higher levels of motivation to quit (OR = 1.2, CI = 1.1, 1.4) also had higher odds of agreeing that e-cigarettes are safer to use than tobacco cigarettes. All other variables were non-significant.

DISCUSSION

In this sample of adult welfare recipient smokers, 77% of participants were aware of e-cigarettes and of those, 37% reported trying an e-cigarette within the past 12 months. To our knowledge this is one of the first studies to examine e-cigarette awareness, use and perceptions within a disadvantaged sample in Australia. Most participants reported obtaining e-cigarettes from friends or strangers or from a tobacco shop (tobacconist). Trying e-cigarettes within the past 12 months was associated with positive perceptions of the safety of e-cigarettes and e-cigarettes as an aid to quit smoking. Additionally, higher motivation to quit smoking was also associated with positive perceptions of the safety and effectiveness of e-cigarettes to help smokers quit.

Levels of awareness reported in the current study are comparable to levels reported in a study conducted with a representative sample of the Australian population in 2014 and slightly lower than estimates within the UK (2014), USA and Canada (2013). Estimates of e-cigarette trial in the current sample were slightly lower (36%) than estimates of ever use in a national sample of current smokers with a mental health condition in the USA (40%) .

Obtaining e-cigarettes from a friend or stranger reflects research that shows that people first try e-cigarettes on their friends’ or family’s recommendation. Both initiation and cessation of tobacco use is known to be influenced by social networks, and this may be occurring fore-cigarette use.
Consistent with previous literature, e-cigarettes were perceived as safer to use than tobacco cigarettes\textsuperscript{30,31} and as aids to help individuals quit smoking tobacco cigarettes\textsuperscript{31,32} by a large proportion of the sample. However, around half of the sample appears misinformed or unsure about whether e-cigarettes are less risky than cigarettes. This reflects data from the UK suggesting that while usage rates have increased, individuals still report uncertainty regarding the safety of e-cigarettes compared to tobacco cigarettes\textsuperscript{33}. Also consistent with the previous literature, ever trying e-cigarettes was associated with positive perceptions of the safety and effectiveness of e-cigarettes to help smokers quit\textsuperscript{31}.

Motivation to quit tobacco smoking was significantly associated with ever trying e-cigarettes. This reflects research that suggests smokers experiencing forms of disadvantage including substance use disorders and mental health conditions may be more likely to ever use e-cigarettes than smokers in the general population\textsuperscript{21,34}.

**Implications**

These results highlight the need for high quality evidence from randomised controlled trials about the safety and effectiveness, or otherwise, of e-cigarettes given current rates of ever use. As awareness of e-cigarettes continues to grow, use may also increase\textsuperscript{28}. If research confirms the effectiveness of e-cigarettes for cessation or harm reduction, they may become a useful intervention for smokers from socioeconomically disadvantaged groups who have not been able to quit smoking with existing methods. It is important to educate the public regarding what is and what is not known about the safety of e-cigarettes based on current scientific knowledge. Similarly, the public should be kept up to date as evidence grows regarding the effectiveness of e-cigarettes as a cessation aid or harm reduction tool. If the eventual evidence supports these potential benefits of e-cigarettes, they may be an important intervention to target to smokers from socioeconomically disadvantaged groups\textsuperscript{19,35}.

Concerns have been raised about the potential for e-cigarettes to increase (and not reduce) the disparities in harms from smoking as new technologies and innovations have historically contributed to increasing disparities in health between disadvantaged and more advantaged individuals who have more capacity to access and benefit from these technologies\textsuperscript{36}. However, our study demonstrates that highly disadvantaged smokers are accessing this technology, even within a country with highly
restrictive laws covering their sale and use. Discussions about how to regulate e-cigarettes should consider the potential impact of such regulations on disadvantaged smokers, who may benefit most from access to less harmful alternatives.

The cost of e-cigarettes may be an important factor to consider. Research to date on the cost of e-cigarettes has shown mixed evidence, with some studies reporting that smokers perceive e-cigarettes to cost less than tobacco cigarettes and other studies reporting the opposite. Within this study, a high proportion of smokers agreed they would switch to e-cigarettes if they were cheaper than tobacco cigarettes. As e-cigarette technology increases and cheaper e-cigarette models emerge on the market, it is important to examine the perceptions of the cost of e-cigarettes and how this effects uptake and stopping use of e-cigarettes within disadvantaged groups, for whom cost may be especially important. Nicotine-containing e-cigarettes are likely to be more effective as a cessation aid than non-nicotine e-cigarettes, however should one gain registration as a therapeutic good, it is likely to only be available on private prescription which may make this option unaffordable for disadvantaged smokers.

**Strengths and limitations**

The main strength of this cross-sectional survey is its large sample of highly disadvantaged smokers with high rates of homelessness, poverty and indigenous status, often referred to as hard-to-reach. This was achieved by approaching smokers through a CSO. While this means that the conclusions are limited to similar populations of disadvantaged Australian smokers seeking assistance from CSO, they may also be generalizable to disadvantaged smokers in other high-income countries where e-cigarettes that contain nicotine are not legal.

As this was a cross-sectional survey, we are unable to determine whether positive experiences with e-cigarettes lead to positive perceptions, or if positive perceptions of e-cigarettes meant participants were more likely to try e-cigarettes. It is plausible that both perceptions and experience affect one another simultaneously.

Another limitation includes the assessment of ever use of e-cigarettes (and not current use). Longitudinal information on the uptake, current use and cessation of e-cigarettes is needed in disadvantaged groups. Additionally, the items used to assess e-cigarette use did not distinguish
between nicotine and non-nicotine e-cigarette models, and the image depicting e-cigarettes was only an early generation “ciga-like” model. Participants may have been more able to recognise newer generation e-cigarette models and thus answered “no” when indicating ever use. Therefore, estimates of ever use in this study may underestimate the true rates of ever use in this sample. This study provides a preliminary investigation into use of e-cigarettes among a highly disadvantaged population of smokers. Future studies should seek to increase the knowledge around current use of e-cigarettes (as definitions of current use are refined^41) and to distinguish between nicotine and non-nicotine models and the subsequent generations of e-cigarette models.

Factors including current use of e-cigarettes, frequency of use, patterns of use including dual use, reasons for use and stopping use of e-cigarettes were not assessed in this study. Future studies should assess these within disadvantaged groups as awareness and use of e-cigarettes increases. Reasons for use may be particularly important to assess as previous research suggests there may be different typologies of e-cigarette users based on the reasons they have for using e-cigarettes^28.

**Conclusion**

Awareness and use of e-cigarettes in this disadvantaged sample were similar to rates reported in a study conducted with a representative sample of the Australian population. Perceptions of e-cigarettes were positive and broadly reflected those reported in the international literature. There is a need for high quality evidence about the safety and effectiveness, or otherwise, of e-cigarettes, to guide appropriate policy-making concerning these products.
