AABR, KS, and MAC are co-inventors on a patent application filed by The University of Queensland describing novel small molecules inhibitors of the NLRP3 inflammasome. However, none of these new molecules are described in the present work, which is limited to the public domain, non-patented compound MCC950. Hence there is no direct conflict of interest in this work describing the role of MCC950 in NASH, but the commercial association with other inhibitors of the inflammasome described in said patent application are declared.
Abbreviations:

Alms1, murine equivalent of Alström gene
BMMs, bone marrow macrophages
CLS, crown-like structures
CTGF, connective tissue growth factor
DAMPS, danger-associated molecular patterns
HMGB1, high mobility group box 1
LPS, lipopolysaccharide
MCD, methionine and choline deficiency
MCS, methionine and choline supplemented
MPO, myeloperoxidase
NAFLD, non-alcoholic fatty liver disease
NASH, non-alcoholic steatohepatitis
NF-κB, nuclear factor kappa-B
NLRP3, NOD-like receptor protein 3
PAMPs, pathogen-associated molecular patterns
Pos, positive
RFU, relative fluorescence unit
ROS, reactive oxygen species
SMA, smooth muscle actin
TLR, Toll-like receptor
Lay summary:
Fatty liver disease caused by overweight with diabetes and high risk of heart attack, termed non-alcoholic steatohepatitis (NASH), is the most common serious liver disease but there is no treatment. The causes of inflammation in NASH may be several, but activation of a protein scaffold within cells termed the inflammasome (NLRP3) has been suggested to play a role. Here we show that cholesterol crystals could be one pathway to inflammasome activation in NASH. We then used a drug called MCC-950 which has already been shown to block NLRP3 activation, in an attempt to reduce liver injury in NASH. This drug partly reversed liver inflammation, particularly in obese diabetic mice that most closely resemble the human context of NASH. In addition, such dampening of liver inflammation in NASH achieved with MCC950 partly reversed liver scarring, the process that links NASH to development of cirrhosis.
Abstract

Background and Aims: NOD-like receptor protein 3 (NLRP3) inflammasome activation occurs in NAFLD. We used the first small molecule NLRP3 inhibitor, MCC950, to test whether inflammasome blockade alters inflammatory recruitment and liver fibrosis in two murine models of steatohepatitis.

Methods: We fed foz/foz and wildtype (Wt) mice atherogenic diet 16 weeks, gavaged MCC950 or vehicle until 24 weeks, then determining NAFLD phenotype. In mice fed methionine/choline deficient (MCD) diet, we gavaged MCC950 or vehicle 6 weeks and determined effects on liver fibrosis.

Results: In vehicle-treated foz/foz mice, hepatic expression of NLRP3, pro-IL-1β, active caspase-1 and IL-1β increased at 24 weeks, in association with cholesterol crystal formation and NASH pathology; plasma IL-1β, IL-6, MCP-1, ALT/AST all increased. MCC950 treatment normalized hepatic caspase 1 and IL-1β expression, plasma IL-1β, MCP-1 and IL-6, lowered ALT/AST, and reduced the severity of liver inflammation including designation as NASH pathology, and liver fibrosis. In vitro, cholesterol crystals activated Kupffer cells and macrophages to release IL-1β; MCC950 abolished this, and associated neutrophil migration. MCD diet-fed mice developed fibrotic steatohepatitis; MCC950 suppressed the increase in hepatic caspase 1 and IL-1β, lowered numbers of macrophages and neutrophils in the liver, and improved liver fibrosis.

Conclusion: MCC950, an NLRP3 selective inhibitor, improved NAFLD pathology and fibrosis in obese diabetic mice, and this is potentially attributable to blockade of cholesterol crystal-mediated NLRP3 activation in myeloid cells. MCC950 reduced liver fibrosis in MCD-fed mice. Targeting NLRP3 is a logical direction in pharmacotherapy of NASH.
Non-alcoholic fatty liver disease (NAFLD) increases standardised mortality from cardiovascular events, common cancers, cirrhosis and hepatocellular carcinoma [1,2]. Adverse liver outcomes are confined to the 10-25% of NAFLD patients with liver fibrosis, particularly with the pathology of steatohepatitis (NASH) [3,4]. NASH occurs when overnutrition is complicated by insulin resistance and metabolic syndrome [2,5,6], particularly with a personal or family history of type 2 diabetes. Despite these connections, detailed mechanisms linking metabolic obesity to liver pathology are unclear. The most compelling concept is that hepatocyte injury results from lipotoxicity, a consequence of accumulated toxic lipid species [6,7]. Lipotoxicity, via release of danger-activated molecular patterns (DAMPs) from injured hepatocytes, and the gut microbiome via release of pathogen-activated molecular patterns (PAMPs) such as lipopolysaccharide (LPS) activate innate immunity to cause liver inflammation [8-10].

Innate immunity involves signalling via pattern recognition receptors, such as the Toll-like receptors (TLRs). During the last few years another trigger for liver inflammation in NAFLD has been identified as the NOD-like receptor protein 3 (NLRP3) inflammasome [11-22]. Inflammasomes are multiprotein scaffolds that respond to noxious signals (PAMPs, DAMPs) to recruit the adapter protein ASC and pro-caspase 1, thereby activating caspase 1 by autocatalysis [18,21,22]. Since the outcomes include programmed cell death (pyroptosis), inflammation and fibrosis [16,19,22], the threshold for inflammasome activation requires a double activation signal. For the NLRP3 inflammasome, which is highly expressed in liver, the first signal is often LPS, but TNF-α and IL-1β are among other signal-1 molecules pertinent to NASH [16,19,22]. Factors that potentially provide the second signal include ATP, amyloid, uric acid and cholesterol crystals [23,24], while oxidative stress and potassium ion transport are related to the effector pathways of NLRP3 activation. In dietary and nutrient deficiency fatty liver diseases, increased hepatic expression of Nlrp3, Asc and Casp1 accompanies liver inflammation [11,14,18,25]. NLRP3 activation occurs in human NASH [11,20], while experiments in Nlrp3−/−, Casp1−/− and Asc−/− mice indicate NLRP3 activation is mechanistically important for NAFLD [11,13,20]. Until now, however, it has not been possible to test whether requirement for NLRP3 activation in the initiation and perpetuation of liver inflammation in NASH is obligatory, using intervention experiments. Further, we note that earlier studies did not use mice with metabolic syndrome, the invariable context of NASH in humans [1,2,5,6]. Development of MCC950 as a first-in-class, highly potent and
selective small molecule inhibitor of NLRP3 [26], and characterization of a hyperphagic obesity mouse model of NASH linked to type 2 diabetes and metabolic syndrome [27-30], allowed us to conduct such studies, as reported here.

Cholesterol crystals activate NLRP3 in LPS-exposed macrophages [23,24]. Recently, cholesterol crystals have been observed in livers of human NASH and murine NASH models, including the one used for the present experiments [27,31]. Here, we first showed that cholesterol crystals activate NLRP3 in LPS-exposed Kupffer cells (KCs), bone marrow macrophages (BMMs), but minimally (if at all) in hepatocytes; 10 nM MCC950 inhibited such activation, as well as resultant neutrophil migration in response to conditioned media from macrophages exposed to cholesterol crystals. We then conducted simultaneous studies in San Diego, CA and Canberra, Australia to test efficacy of MCC950 for preventing or reversing liver injury, inflammation and fibrosis in two entirely different models of experimental steatohepatitis. Appetite-defective foz/foz mice are an over- nutrition model in which NASH accompanies onset of obesity and its metabolic complications, including diabetes and hypercholesterolemia [27-30]. The methionine and choline deficient (MCD) dietary model causes severe steatohepatitis with liver fibrosis, whose pathogenesis involves hepatic oxidative stress as observed in human NASH [32,33]. Taken together, these novel findings provide robust support for the proposal that pharmacological blockade of NLRP3 activation in the liver can improve NASH pathology and modulate other forms of steatohepatitis, including its most critical outcome of liver fibrosis.

Methods

Animal models

Animal experiments were approved by Animal Experimentation Ethics Committees of Australian National University (Canberra) and UC San Diego.

Atherogenic diet-fed foz/foz model. Groups (n=11-13) of female Alms1 mutant (foz/foz) mice or wildtype (Wt) littermates were fed atherogenic diet (23% fat, 45% carbohydrate, 20% protein, 0.2% cholesterol; SF03020, Specialty Feeds, Glenn Forrest, Western Australia) for 16 weeks, when foz/foz mice weighed >60 g and exhibited hyperinsulinemia, diabetes, hypertension, hypercholesterolemia, hypoadiponectinemia, and NASH with fibrosis [29,30]. From 16 weeks, mice were gavaged MCC950 (20 mg/kg body weight) or vehicle (0.9% NaCl) every day, 5 days/week until 24 weeks (Suppl. Fig. 1A). Venous blood (~0.2 mL) were
obtained by cheek bleeding at 15 and 20 weeks. At 24 weeks, mice were fasted 4h to determine blood glucose (Accu-Check glucometer, Roche Diagnostics), anesthetized (ketamine and xylazine), plasma and liver collected and processed for histological and molecular readouts [29,30].

**Methionine and choline deficient diet model.** Since 2000 [32], this model has been used extensively to cause severe steatohepatitis and fibrosis, resembling human NASH pathology [28]. Groups (n=8) of 8-week-old male C57BL/6(B6) mice were placed on MCD diet (TD90262, Teklad Mills, Madison, WI), controls were fed the identical diet supplemented with methionine and choline (MCS) (TD94149, Teklad Mills). MCD-fed mice and MCS controls were divided into groups receiving MCC950 (10 mg/kg body weight in 0.9% NaCl every day for 5 days, followed by 20 mg/kg every second day up to 6 weeks), or vehicle by gavage. At the end of experiments, mice were anesthetized, liver and plasma collected [19,20]. In a second experiment, mice (n=5-6/group) were fed MCD diet for 6 weeks, during the last 2 weeks they were gavaged every day with MCC950 (20 mg/kg) or vehicle before experiments were completed.

**Cholesterol crystal preparation**

Hydrated cholesterol crystals, prepared as described [24], were homogenized to obtain crystals <10 μm in diameter, and suspended in culture media before addition to cells.

**Isolation and culture of bone marrow-derived macrophages, primary hepatocytes, Kupffer cells, and neutrophil chemotaxis studies**

Using 8-10 week-old female B6 mice, bone marrow cells were extracted and differentiated (7 days) into BMMs in murine L929 media (diluted 1:10 in RPMI with 10% FBS). Morphology was checked by Wright-Giemsa staining, phenotype by Mac1 and F4/80 double-positive cells (flow cytometry). In selected experiments, we isolated/cultured BMMs from Tlr4−/− mice (gift of Shaun Summers, Monash Medical Centre, Clayton, VIC), and Myd88−/− mice (Australian Phenomics Facility, Canberra), all B6. Hepatocytes were isolated by collagenase perfusion [30,34], seeded onto plates coated with collagen (Gibco, Carlsbad, CA), and cultured in Williams’ E with 1% bovine serum albumin (Sigma-Aldrich, St Louis, MO), 10 mM HEPES, 10 mM nicotinamide, 100 U/mL penicillin and 100 μg/mL streptomycin. KCs were isolated from non-parenchymal cells of collagenase-perfused mouse liver [35]. Following pre-incubation with LPS (50 pg/mL) for 1h (followed by washing), cholesterol crystals were
added at concentrations indicated in figure legends. We measured NLRP3 activation and inhibition by 10 nM MCC950 as IL-1β release into culture medium (ELISA). Neutrophil chemotaxis was performed as described [36] using recombinant mouse(rm)-TNFα as positive chemoattractant.

**Analysis of plasma proteins**
Plasma insulin, adiponectin, monocyte chemoattractant protein (MCP) -1, IL-1β, IL-6 and IL-18 were measured by ELISAs (Insulin, Millipore, USA; others, R&D Systems, Minneapolis, MN).

**Assessment of liver injury, liver pathology and fibrosis**
Plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were assayed by auto-analyser (Clinical Chemistry, ACT Pathology). Liver samples were fixed in 10% neutral-buffered formalin and paraffin embedded. H&E-stained liver sections were assessed blind by an experienced liver pathologist (MMY) for steatosis, inflammation and ballooning, combined as NAFLD activity score (NAS), and designation as: “definite NASH”, “borderline NASH”, “NAFLD but not NASH”, or “not NAFLD”. To demonstrate fibrosis, liver sections were stained 2h with picric acid containing 0.1% fast green and 0.1% Sirius red. Fibrosis severity determined by collagen densitometry [30,37].

**Hepatic proteins**
Hepatic proteins were estimated by Western immunoblot, [19,20,29,30,37] (antibody conditions provided on request). For tissue protein expression studies, immunohistochemistry was performed [12,19,20,30,31,37]. NF-κB p65 positive nuclei (in hepatocytes and inflammatory cells) and MPO positive neutrophils were counted and numbers expressed per 100 hepatocytes. F4/80-positive staining was used to identify activated macrophages and KCs surrounding steatotic hepatocytes to form crown-like structures (CLS). For each liver section, 10 random fields (400x magnification) were counted and mean value used.

**Hepatic mRNA expression**
We determined hepatic expression of specific mRNAs by reverse-transcriptase quantitative PCR (RT-qPCR), following extraction of total RNA from liver tissue [19,20]. Primer sequences in Suppl. Table 1. Expression of mRNA was relative to β2-microglobulin (B2M).

Statistical analyses
For experiments involving 2 groups where distribution of data was not clearly parametric, Mann-Whitney U tests were performed with GraphPad Prism Software Inc, CA, Version 5.03. For experiments involving 3 or more groups, data were evaluated using one-way ANOVA with multiple comparison post hoc analysis. Data are expressed as mean ± SEM, or as absolute number or percentage for categorical variables. The number of animals or measurements in each group is indicated in the figure legends. The significance level was set at α = 5% for all comparisons.

Results
Cholesterol crystals activate NLRP3 in wildtype but not Myd88−/− macrophages, Kupffer cells and hepatocytes  The high free cholesterol content of human and foz/foz mouse NASH livers [30,38-41] results in cholesterol crystallization [27,31]. Cholesterol crystals activate NLRP3 in LPS-primed macrophages [23,24]. We first demonstrated such activation (measured as IL-1β release) (Fig. 1A) and showed it is substantially inhibited by 10 nM MCC950 (Fig. 1B). Culture supernatant from crystal-exposed BMMs stimulated neutrophil chemotaxis; prior addition of MCC950 blocked this effect (Fig. 1C). Addition of cholesterol crystals to KCs produced similar results, albeit the magnitude of IL-1β release was less (Fig. 1D vs 1B). We conducted identical experiments on BMMs from Tlr4−/− or Myd88−/− mice. Lack of TLR4 reduced IL-1β release, while MYD88 was essential for LPS priming of macrophages to release IL-1β in response to cholesterol crystals (Fig. 1A). Addition of crystals to LPS-primed hepatocytes appeared to cause dose-dependent IL-1β release, but the quantum was much less than for KCs and close to the limit of sensitivity for IL-1β detection (Fig. 1E vs 1D).

MCC950 exhibits good bioavailability after gavage to mice  MCC950 has excellent microsomal stability, does not inhibit major CYP isoforms, has 70% oral bioavailability and a half-life of 3.2 h after oral dosing in mice [26]. For logistic and animal health reasons we chose to conduct daily administration of drug or vehicle (rather than twice daily). We
therefore measured blood levels following gavage of a single dose (20 mg/kg body weight) to foz/foz or Wt mice. As shown in Suppl. Fig. 1B, high blood levels of MCC950 were evident at 1h with no change by 4h and appreciable trough levels at 24h.

**Treatment with MCC950 blocks hepatic NLRP3 expression and activation in NASH** To test whether MCC950 can block cholesterol crystal-mediated activation of NLRP3 in intact livers with NASH (crystals shown in Suppl. Fig. 2A), we fed foz/foz mice atherogenic diet 16 weeks to cause NASH [29,30,37], then gavaged animals with MCC950 or vehicle another 8 weeks (experimental design summarized in Suppl. Fig 1A). Livers of vehicle-treated foz/foz mice with NASH exhibited substantial increases in NLRP3 (Fig. 2A), active caspase 1 (but not pro-caspase 1), pro-IL-1β and IL-1β (Fig. 2B-F). MCC950 reduced expression of all proteins (except pro-IL-1β) to values in vehicle-treated Wt mice (Figs. 2A-F). At 24 weeks, there was a significant increase in circulating IL-1β in vehicle-treated foz/foz mice with NASH compared to Wt mice with simple steatosis; MCC950 prevented this increase (Fig. 3A). There were no significant changes in IL-18 between groups (Fig. 3B).

**Treatment with MCC950 ameliorates liver injury and inflammation in two murine steatohepatitis models** In atherogenic diet-fed foz/foz mice gavaged with vehicle, plasma ALT and AST increased substantially at 16 weeks compared to Wt mice fed the same diet, with further rise by 24 weeks (Fig. 3C,D). Administration of MCC950 abrogated the increase in ALT and AST between 16 and 24 weeks in foz/foz mice, and also the moderate further increase in Wt mice (Fig. 3C,D). MCC950 did not cause weight loss in foz/foz or Wt mice (Suppl. Fig. 3A). There was also no reduction of hepatomegaly (Suppl. Fig. 3B), or in fasting blood glucose, plasma insulin, adiponectin, cholesterol, or triglyceride (Suppl. Fig. 3C-F). Consistent with this lack of effect on metabolic indices and our earlier observation that insulin drives hepatic cholesterol accumulation [30], there was no difference in cholesterol crystal numbers between livers of MCC950- and vehicle-treated foz/foz mice (Suppl. Fig. 2B). In contrast to this lack of effect on the “metabolic drivers” of NASH pathogenesis [6], MCC950 lowered plasma MCP-1 and IL-6 levels (Fig. 3E,F). Likewise, whereas blinded semiquantitative analysis of liver histology showed no effect of MCC950 on steatosis score (Fig. 4A(i)), there was reduction of liver inflammation (Fig. 4B), and a strong trend (not significant) for less ballooning (Fig. 4A(ii)) and lower overall NAFLD activity score (NAS) (Fig. 4A(iii)). The effects of MCC950 on liver inflammation were supported by
significant (~50%) suppression of nuclear NF-κB p65 expression (in hepatocytes and inflammatory cells), and in the number of MPO-positive cells (neutrophils) and F4/80-positive cells (macrophages/activated KCs forming crown-like structures [CLS]) (Fig. 4C-E). Importantly, global assessment of liver pathology as “definite NASH”, which was 64% in vehicle-treated foz/foz mice, appeared to be less (18%) in MCC950-treated animals, although likely because of the relatively small numbers this apparent difference was not significant (Table 1).

The MCD model shows severe steatohepatitis but is not caused by over-nutrition or associated with insulin resistance [28,32,42,43]. Levels of active caspase 1 and IL-1β, and Asc, Casp1 and Il1b mRNA expression were all higher in livers of MCD-fed vs MCS-fed mice. Gavaging MCC950 for 6 weeks significantly lowered their expression (Fig. 5A). As reported [28,32,42,43], MCD diet-fed mice lost weight compared with controls, but MCC950 exerted no separate effect on body weight (data not shown). Livers of MCD-fed mice showed steatosis with severe lobular inflammation (Fig. 5B), though at the dose used for these experiments (effectively half that used for foz/foz mice – see Methods) there was no effect of MCC950 on plasma ALT. Hepatic infiltration with neutrophils (MPO) and total macrophages (F4/80) indicated by immunohistochemistry (Fig. 5B), and relevant mRNA transcripts for F4/80, MPO and infiltrating macrophages (Ly6c mRNA) increased in MCD vs MCS mouse liver (Suppl. Fig. 4); MCC950 partially (significantly) corrected over-expression of these inflammatory markers (Fig. 5B; Suppl. Fig. 4).

**MCC950 retards development of liver fibrosis in MCD diet-induced steatohepatitis and in foz/foz mice with NASH**  
As expected, MCD diet-fed mice showed increased collagen deposition by Sirius red staining (Fig. 5C), with corresponding increases in Coll1a1, connective tissue growth factor (Ctgf) and tissue inhibitor of matrix metalloproteinase 1 (Timp1) transcripts compared to MCS controls (Fig. 5D). Treatment with MCC950 for 6 weeks appeared to decrease hepatic fibrosis by Sirius red densitometry (Fig. 5C), and significantly reduced hepatic expression of the aforementioned pro-fibrotic markers (Fig. 5D). In case the dose regimen selected for these experiments was suboptimal (compared with that used for foz/foz mouse experiments), we repeated this experiment using the same dose (20 mg/kg body weight) as in foz/foz mice administered by gavage once a day for 2 weeks, starting 4 weeks after mice had been fed MCD diet. There appeared to be substantial Sirius
red-positive material in liver sections of vehicle-treated controls and very little in MCC950-treated mice, although the apparent difference in collagen density fell short of significance ($p=0.056$) (Suppl. Fig. 5B).

An ideal anti-inflammatory approach to NASH treatment would not only prevent fibrosis development it would also arrest or reverse established liver fibrosis. To test this, we administered MCC950 to $foz/foz$ mice already fed atherogenic diet 16 weeks (Suppl. Fig. 1A), at which time fibrotic NASH is established, as confirmed by substantial collagen deposition (Sirius red densitometry) in vehicle-treated mice (Fig. 6A,B). Following treatment for 8 weeks with the NLRP3 inhibitor, there was ~33% reduction in macroscopic liver fibrosis compared to vehicle-treated controls (Fig. 6A,B), accompanied by significant (but incomplete) suppression of collagen I expression, reduced HSC activation (as alpha-smooth muscle actin [$\alpha$-SMA] expression) and hepatic CTGF (Fig. 6C-F).

**Discussion**

The most important finding in these studies is that pharmacological inhibition of NLRP3 in vivo reduces liver inflammation and hepatocyte injury in metabolic syndrome-related NAFLD with significant reduction in resultant liver fibrosis. Hepatic NLRP3 expression increases during development of experimental and clinical NAFLD [11,13,14,18-20,25], and mice deficient in NLRP3 ($Nlrp3^{-/-}$) or its essential components ($Asc^{-/-}$ and $Casp1^{-/-}$ mice) are protected against fatty liver disease caused by high fat or nutrient-deficient diets [12,14,20]. The present experiments employed atherogenic diet-fed $foz/foz$ mice, a NASH model in which animals develop severe obesity, metabolic syndrome and diabetes. In this clinically relevant model, we showed induction of NLRP3 and evidence of its activation in liver (active caspase 1, IL-1$\beta$) in mice with NASH; MCC950 blocked such activation of the NLRP3 inflammasome in liver tissue, with resultant suppression of macrophage (with CLS formation) and neutrophil recruitment. Pharmacological NLRP3 blockade also reduced hepatic expression of pro-IL-1$\beta$ and normalized hepatic and circulating IL-1$\beta$, IL-6 and MCP-1 levels; pro-IL-1$\beta$ and MCP-1 synthesis is regulated by NF-\kappaB, whose nuclear expression was also suppressed substantially in these experiments [9,18,22,44]. Hepatic NLRP3 expression was also suppressed by MCC950 treatment, most likely because
decreased production of IL-1β was, at least in part, responsible for the observed dampening of NF-κB activation. In the MCD model, NLRP3 inflammasome inhibition similarly reduced macrophage and neutrophil infiltration into the liver. Together, these data provide compelling evidence to support earlier work in gene-deleted and dietary models for a central pro-inflammatory role of NLRP3 activation in pathogenesis of NASH.

Our in vitro studies combined with the observed effects of MCC950 in vivo may provide some insight into why NLRP3 is activated in NASH livers. A dual signal is required to promote NLRP3 macromolecular assembly and caspase 1 activation [16,18,21,22]. It seems possible that gut-derived PAMPs, such as LPS used in our in vitro experiments, play such a role in NASH [45,46]. Additional signal-1 molecules include TNF-α and IL-1β. Signal-2 molecules relevant to NASH include crystals and ATP. We showed earlier, and confirmed here (Suppl. Fig. 2A), that cholesterol crystals form in hepatocytes in foz/foz mice as well as human NASH [27,31]. These crystals could play their most critical role when hepatocytes undergo necrotic cell death as part of lipotoxicity [34], releasing crystals into the surrounding tissue [47] where they are taken up by KCs and infiltrating macrophages, thus activating NLRP3 with release of large quanta of IL-1β. Here we used cholesterol crystals to activate NLRP3 in macrophages and Kupffer cells in vitro, simulating the likely uptake of such crystals in the intact liver. We showed that MYD88 is an obligatory signalling intermediate for this pathway, and that it is augmented by TLR4 signaling. A role for TLR4 in experimental NASH receives strong support from other studies. For example, we and Li et al have shown it is part of a high mobility group box 1 (HMGB1) dependent feed-forward pathway of lipotoxic injury to hepatocytes in the early stages of NASH [34,48]. The mechanisms for interaction between TLR4 and NLRP3 include NF-κB-dependent induction of NLRP3 and pro-IL-1β. In turn, IL-1β binding its cognate receptor activates NF-κB [16,22,44], leading to a vicious cycle of pro-inflammatory signalling. It remains possible that HMGB1 and other DAMPs activate both pathways simultaneously, but this requires further studies.

Our results do not support the contention that NLRP3 influences metabolic disorder relevant to NASH pathogenesis [45,46]. Specifically, MCC950 did not alter body weight or the very high plasma insulin, fasting blood glucose, plasma cholesterol and low plasma adiponectin
levels in obese foz/foz mice, all of which contribute mechanistically to NASH [1,2,5-7]. The different conclusions reached by earlier workers may be due to the breeding of mice with a constitutive NLRP3 deletion leading to microbial dysbiosis [45,46], which is not seen when NLRP3 is inhibited in adult mice. Our data also fail to support a proposed role of IL-1β in contributing to hepatocyte fat deposition in NASH [17,49]. Instead, the beneficial effects of MCC950 inhibition against steatohepatitis were limited to abrogation of the pro-inflammatory effects of hepatic NLRP3 activation, not to any effect on steatosis or cholesterol crystal deposition which remained unaltered.

The operation of NLRP3 as a pathogenic mechanism in the MCD model indicates that cholesterol crystals are not the only pathway to inflammasome activation in steatohepatitis. Release of ATP from necrotic cells, HMGB1, histones, amyloid and uric acid crystals can each activate NLRP3 via separate but potentially overlapping pathways [15,18,21,22,44], while reactive oxygen species (ROS) and potassium ion fluxes are linked to the effector stages of NLRP3 activation [22]. We and others [42,44] have demonstrated that the predominant lipidomic abnormality in the MCD-fed mice is accumulation of saturated free fatty acids, differing from foz/foz mice and human NASH in which free cholesterol is the toxic lipid that distinguishes NASH from simple steatosis [30,38-41]. Saturated free fatty acids and free cholesterol both cause lipotoxicity via JNK1 activation [34,50], leading to mitochondrial injury with generation of ROS. Sources of oxidative stress have been characterized in the MCD model and in human NASH, such as induction of CYPs 2E1 and 4A [32,33]. Whether ROS are sufficient to act alone as second signal (with LPS, TNF-α or IL-1β as signal-1) or augment other inflammasome activators, such as ATP and cholesterol crystals, requires further study.

Liver fibrosis predicts adverse liver outcomes in NAFLD [1-4], so an emphasis of these studies, was to establish whether NLRP3 inhibition reduces liver fibrosis in steatohepatitis. We tested this in two entirely different models [28], because several pathways may interact to promote hepatic fibrogenesis in steatohepatitis. NLRP3 inhibition may combat liver fibrosis because dampening liver inflammation lowers expression of pro-fibrotic cytokines and growth factors (TNF-α, TGF-β, CTGF), and IL-1β may be directly pro-fibrogenic [12,19,44]. Indeed, administration of anakinra, an IL-1β receptor antagonist, improved liver fibrosis in
experimental alcoholic hepatitis [17]. Our present results in MCD-fed mice demonstrate that MCC950, an orally available small molecule, affords substantial (though incomplete) protection against hepatic fibrosis when administered at the same time as the disease-inducing diet over 6 weeks, and even when administered for 2 weeks of such a regimen there appears to be moderate (albeit not significant) reduction of collagen deposition. In the more protracted obese/diabetic foz/foz model, the 8-week data from 16 to 24 weeks complement this finding, and indicate the potential for NLRP3 inhibitor treatment to arrest or resolve of liver fibrosis once NASH is established. Further experiments with introduction of MCC950 therapy at a later time, are required to determine to test the extent to which NLRP3 blockade reverses advanced stage liver fibrosis in NASH.

In summary, we show here that MCC950, a first-in-class potent and specific NLRP3 inhibitor, improves liver injury, substantially reduces hepatic infiltration with macrophages and neutrophils and modulates fibrotic progression of steatohepatitis in two different models. We demonstrated by tissue studies that these effects resulted from substantial reduction of NLRP3 activation in the liver. It remains possible that NLRP3 activation proceeds in concert with other pro-inflammatory pathways, such as lipotoxicity, oxidative stress and TLR4, but a role for NLRP3 and IL-1β on metabolic regulation and hepatic lipid deposition is not supported by the present findings. While the effect of MCC950 on NASH fibrosis in these models is encouraging, the full potential of inflammasome blockade may exceed what we observed here as MCC950, which is a test compound for proof-of-principal studies, does not have optimal pharmacokinetics for once a day oral dosing. Development of second generation NLRP3 inhibitors optimized for liver bioavailability and human use will allow testing of whether these agents provide pharmacological resolution of NASH, and whether this novel approach will reverse significant liver fibrosis, its most important outcome.

Fig. 1. Cholesterol crystals provoke IL-1β release and neutrophil recruitment by macrophages and Kupffer cells, which is inhibited by MCC950. (A) Effects of cholesterol crystals on IL-1β release for LPS-primed bone marrow macrophages (BMM) from wildtype (Wt), Tlr4−/−, and Myd88−/− mice. (B) MCC950 (10 nM) inhibits IL-1β production from Wt BMMs. (C) Enriched culture medium from crystal activated BMMs stimulates neutrophil chemotaxis. (D) Cholesterol crystals stimulate IL-1β release from Kupffer cells, but (E) minimally in hepatocytes. *P<0.05 versus no crystals. ∆P<0.05 versus Wt. *P<0.05 MCC950 versus untreated, by Mann-Whitney U test, n=9-12.

Fig. 2. Effects of conditions causing NASH on hepatic expression of NLRP3, pro-caspase 1, active caspase 1, pro-IL-1β and IL-1β. (A) NLRP3 in wildtype (Wt) and foz/foz mice after 24 weeks atherogenic diet, and gavage during the last 8 weeks with vehicle (saline) or MCC950. (B) Hepatic pro-caspase 1 (p45), (C) active caspase 1 (p10), (D) pro-IL-1β (p30), and (E) IL-1β (p17). (F) Representative Western blot analyses from same experiments, with heat shock protein 90 (HSP90) as loading controls. *P<0.05 versus Wt. #P<0.05 MCC950 versus vehicle, by one-way ANOVA, n=6-10 animals/group.

Fig. 3. Effects of MCC950 versus vehicle on circulating cytokines/chemokines and transaminases in mice with NASH. (A) Plasma IL-1β, (B) Plasma IL-18, (C) ALT, (D) AST, (E) macrophage chemotactic protein 1 (MCP-1), (F) IL-6. Same mice as in Fig. 2. *P<0.05 or less versus Wt. #P<0.05 MCC950 versus vehicle, by one-way ANOVA, n=11-13 animals/group, same animals as in Fig. 2.

Fig. 4. MCC950 reverses NASH pathology. (A) (i) Steatosis, (ii) hepatocyte ballooning, and (iii) NAFLD activity score (NAS) in Wt and foz/foz mice after 24 weeks atherogenic diet, and gavage during last 8 weeks with vehicle or MCC950. (B) Representative H&E-stained liver sections demonstrating inflammation in atherogenic foz/foz mouse liver (vehicle) is abolished by MCC950, with reduction of lobular inflammation score. (C) NF-κB activation (nuclear p65) is suppressed, as are, (D) myeloperoxidase [MPO]) positive neutrophils, and (E) F4/80 positive macrophages and Kupffer cells. Same experiments as Figs. 2 and 3.
